# Inference in first-order logic: just a taste 

Dr. Melanie Martin
CS 4480
November 10, 2010
Based on slides from
http://aima.eecs.berkeley.edu/2nd-ed/slides-ppt/

## Outline

- Reducing first-order inference to propositional inference
- Unification
- Generalized Modus Ponens
- Forward chaining
- Backward chaining
- Resolution

## Inference with Quantifiers

- Universal Instantiation:
- Given $\forall X$ person $(X) \Rightarrow$ likes(X, sun)
- Infer person(john) $\Rightarrow$ likes(john,sun)
- Existential Instantiation:
- Given $\exists x$ likes(x, sun)
- Infer: likes(S1, sun)
- S1 is a "Skolem Constant" that is not found anywhere else in the KB and refers to (one of) the individuals that likes sun.

## Universal instantiation (UI)

- Every instantiation of a universally quantified sentence is entailed by it:
$\frac{\forall v a}{\text { Subst(\{v/g\}, a) }}$
for any variable $v$ and ground term $g$
- E.g., $\forall x \operatorname{King}(x) \wedge \operatorname{Greed}(x) \Rightarrow$ Evil( $(x)$ yields:

King(John) ^ Greedy(John) $\Rightarrow$ Evil(John)
King(Richard) $\wedge$ Greedy(Richard) $\Rightarrow$ Evil(Richard)
King $($ Father $(J o h n)) \wedge$ Greedy (Father(John)) $\Rightarrow \operatorname{Evil}($ Father(John))

## Existential instantiation (EI)

- For any sentence $a$, variable $v$, and constant symbol $k$ that does not appear elsewhere in the knowledge base:
$\frac{\exists v a}{\operatorname{Subst}(\{v / k\}, a)}$
- E.g., $\exists x$ Crown $(x) \wedge$ OnHead( $x$,John) yields:

Crown $\left(C_{1}\right) \wedge$ OnHead( $C_{1}$,John $)$
provided $C_{1}$ is a new constant symbol, called a Skolem constant

## Reduction to propositional inference

Suppose the KB contains just the following:
$\forall x \operatorname{King}(x) \wedge \operatorname{Greedy}(x) \Rightarrow \operatorname{Evil}(x)$
King(John)
Greedy(John)
Brother(Richard,John)

- Instantiating the universal sentence in all possible ways, we have:

King(John) ^ Greedy(John) $\Rightarrow$ Evil(John)
King(Richard) $\wedge$ Greedy(Richard) $\Rightarrow$ Evil(Richard)
King(John)
Greedy(John)
Brother(Richard,John)

- The new KB is propositionalized: proposition symbols are

King(John), Greedy(John), Evil(John), King(Richard), etc.

## Reduction contd.

- Every FOL KB can be propositionalized so as to preserve entailment
- (A ground sentence is entailed by new $K B$ iff entailed by original $K B$ )
- Idea: propositionalize KB and query, apply resolution, return result
- Problem: with function symbols, there are infinitely many ground terms,
- e.g., Father(Father(Father(John)))

## Reduction contd.

Theorem: Herbrand (1930). If a sentence a is entailed by an FOL KB, it is entailed by a finite subset of the propositionalized KB

Idea: For $n=0$ to $\infty$ do
create a propositional KB by instantiating with depth-n terms
see if $a$ is entailed by this KB
Depth1: john, richard
Depth 2: father(john), father(richard)
Problem: works if $a$ is entailed, loops if $a$ is not entailed
Theorem: Turing (1936), Church (1936) Entailment for FOL is semidecidable (algorithms exist that say yes to every entailed sentence, but no algorithm exists that also says no to every nonentailed sentence.)

## Problems with propositionalization

- Propositionalization seems to generate lots of irrelevant sentences.
- E.g., from:
$\forall x \operatorname{King}(x) \wedge \operatorname{Greedy}(x) \Rightarrow \operatorname{Evil}(x)$
King(John)
$\forall y$ Greedy (y)
Brother(Richard,John)
- it seems obvious that Evil(John), but propositionalization produces lots of facts such as Greedy(Richard) that are irrelevant
- With $p k$-ary predicates and $n$ constants, there are $p \cdot n^{k}$ instantiations.

## Unification

- We can get the inference immediately if we can find a substitution $\theta$ such that $\operatorname{King}(x)$ and $\operatorname{Greedy}(x)$ match King(John) and Greedy(y)
$\theta=\{x / J o h n, y / J o h n\}$ works
- $\operatorname{Unify}(\alpha, \beta)=\theta$ if $\alpha \theta=\beta \theta$

## Unification

- We can get the inference immediately if we can find a substitution $\theta$ such that $\operatorname{King}(x)$ and $\operatorname{Greedy}(x)$ match King(John) and Greedy(y)
$\theta=\{x / J o h n, y / J o h n\}$ works
- $\operatorname{Unify}(\alpha, \beta)=\theta$ if $\alpha \theta=\beta \theta$

| $p$ | $q$ | $\theta$ |
| :--- | :--- | :--- |
| Knows(John,x) | Knows(John,Jane) | $\{x /$ Jane $\}\}$ |
| Knows(John,x) | Knows(y,AJ) |  |
| Knows(John,x) | Knows(y,Mother(y)) |  |
| Knows(John,x) | Knows(x,AJ) |  |

## Unification

- We can get the inference immediately if we can find a substitution $\theta$ such that King(x) and Greedy(x) match King(John) and Greedy(y)
$\theta=\{x / J o h n, y / J o h n\}$ works
- $\operatorname{Unify}(\alpha, \beta)=\theta$ if $\alpha \theta=\beta \theta$

| $p$ | $q$ | $\theta$ |
| :--- | :--- | :--- |
| Knows(John,x) | Knows(John,Jane) | $\{x / J a n e\}\}$ |
| Knows(John,x) | Knows(y,AJ) | $\{x / A J, y / J o h n\}\}$ |
| Knows(John, $x)$ | Knows(y,Mother(y)) |  |
| Knows(John,x) | Knows(x,AJ) |  |

## Unification

- We can get the inference immediately if we can find a substitution $\theta$ such that King(x) and Greedy(x) match King(John) and Greedy(y)
$\theta=\{x / J o h n, y / J o h n\}$ works
- $\operatorname{Unify}(\alpha, \beta)=\theta$ if $\alpha \theta=\beta \theta$

| $p$ | $q$ | $\theta$ |
| :--- | :--- | :--- |
| Knows(John,x) | Knows(John,Jane) | $\{x / J a n e\}\}$ |
| Knows(John,x) | Knows(y,AJ) | $\{x / A J, y / J o h n\}\}$ |
| Knows(John,x) | Knows(y,Mother(y)) | $\{y / J o h n, x / M o t h e r(J o h n)\}\}$ |
| Knows(John,x) | Knows(x,AJ) |  |

## Unification

- We can get the inference immediately if we can find a substitution $\theta$ such that King(x) and Greedy(x) match King(John) and Greedy(y)
$\theta=\{x / J o h n, y / J o h n\}$ works
- $\operatorname{Unify}(\alpha, \beta)=\theta$ if $\alpha \theta=\beta \theta$

| $p$ | $q$ | $\theta$ |
| :--- | :--- | :--- |
| Knows(John, $x)$ | Knows(John,Jane) | $\{x / J a n e\}\}$ |
| Knows(John, $x)$ | Knows(y,AJ) | $\{x /$ AJ,y/John $\}\}$ |
| Knows(John, $x)$ | Knows(y,Mother(y)) | $\{y / J o h n, x / M o t h e r(J o h n)\}\}$ |
| Knows(John, $x)$ | Knows(x,AJ) | $\{f a i l\}$ |

- Standardizing apart eliminates overlap of variables, e.g., Knows( $\left.\mathrm{Z}_{17}, \mathrm{AJ}\right)$

## Unification

When there is more than one unifier:

- To unify Knows(John, $x$ ) and $\operatorname{Knows(y,z),~}$ $\theta=\{y / J o h n, x / z\}$ or $\theta=\{y / J o h n, x / J o h n, z / J o h n\}$
- The first unifier is more general than the second.
- Fewer restrictions
- There is a single most general unifier (MGU) that is unique up to renaming of variables.
MGU $=\{y / J o h n, x / z\}$

## Generalized Modus Ponens

- This is a general inference rule for FOL that does not require instantiation
- GMP "lifts" MP from propositional to firstorder logic
- Key advantage of lifted inference rules over propositionalization is that they make only substitutions which are required to allow particular inferences to proceed

$$
\frac{p 1^{\prime}, p 2^{\prime}, \ldots, p n^{\prime},(p 1 \wedge p 2 \wedge \ldots \wedge p n \Rightarrow q)}{q \theta}
$$

where pi' $\theta=$ pi $\theta \forall i$

- p1' is King(John)
- p2' is Greedy (y)
- $\Theta$ is $\{x / J o h n, y / J o h n\}$
- $q \theta$ is Evil(John)

GMP used with KB of definite clauses (exactly one positive literal)
All variables assumed universally quantified

## Example knowledge base

- The law says that it is a crime for an American to sell weapons to hostile nations. The country Nono, an enemy of America, has some missiles, and all of its missiles were sold to it by Colonel West, who is American.
- Prove that Col. West is a criminal

## Example knowledge base contd.

... it is a crime for an American to sell weapons to hostile nations:
American $(x)$ ^ Weapon $(y)$ ^Sells $(x, y, z)$ ^ Hostile $(z) \Rightarrow \operatorname{Criminal}(x)$
Nono ... has some missiles, i.e., $\exists x$ Owns(Nono,x) ^ Missile(x):
Owns(Nono, $M_{1}$ ) and $\operatorname{Missile}\left(M_{1}\right)$
... all of its missiles were sold to it by Colonel West
Missile ( $x$ ) ^ Owns(Nono, $x$ ) $\Rightarrow$ Sells(West, $x$, Nono)
Missiles are weapons:
Missile ( $x$ ) $\Rightarrow$ Weapon $(x)$
An enemy of America counts as "hostile":
Enemy( $x$,America) $\Rightarrow$ Hostile ( $x$ )
West, who is American ...
American(West)
The country Nono, an enemy of America ...
Enemy(Nono,America)

## Forward chaining algorithm

## function FOL-FC-ASk $(K B, \alpha)$ returns a substitution or false

repeat until new is empty
new $\leftarrow\}$
for each sentence $r$ in $K B$ do
$\left(p_{1} \wedge \ldots \wedge p_{n} \Rightarrow q\right) \leftarrow$ Standardize-APART $(r)$
for each $\theta$ such that $\left(p_{1} \wedge \ldots \wedge p_{n}\right) \theta=\left(p_{1}^{\prime} \wedge \ldots \wedge p_{n}^{\prime}\right) \theta$ for some $p_{1}^{\prime}, \ldots, p_{n}^{\prime}$ in $K B$

$$
q^{\prime} \leftarrow \operatorname{SUBST}(\theta, q)
$$

if $q^{\prime}$ is not a renaming of a sentence already in $K B$ or new then do add $q^{\prime}$ to new $\phi \leftarrow \operatorname{Unify}\left(q^{\prime}, \alpha\right)$ if $\phi$ is not fail then return $\phi$
add new to $K B$
return false

## Forward chaining proof

## Forward chaining proof

Hostile(Nono)

Enemy (Nono,America)

## Forward chaining proof

## Properties of forward chaining

- Sound and complete for first-order definite clauses
- Datalog $=$ first-order definite clauses + no functions
- FC terminates for Datalog in finite number of iterations
- May not terminate in general if $a$ is not entailed
- This is unavoidable: entailment with definite clauses is semidecidable

## Efficiency of forward chaining

Incremental forward chaining: no need to match a rule on iteration $k$ if a premise wasn't added on iteration k-1
$\Rightarrow$ match each rule whose premise contains a newly added positive literal

Matching itself can be expensive:
Database indexing allows $\mathrm{O}(1)$ retrieval of known facts

- e.g., query $\operatorname{Missile}(x)$ retrieves $\operatorname{Missile}\left(M_{1}\right)$

Forward chaining is widely used in deductive databases

## Backward chaining algorithm

function FOL-BC-Ask $(K B$, goals, $\theta)$ returns a set of substitutions inputs: $K B$, a knowledge base goals, a list of conjuncts forming a query
$\theta$, the current substitution, initially the empty substitution $\}$
local variables: ans, a set of substitutions, initially empty
if goals is empty then return $\{\theta\}$
$q^{\prime} \leftarrow \operatorname{SuBST}(\theta, \operatorname{First}($ goals $))$
for each $r$ in $K B$ where $\operatorname{Standardize-Apart}(r)=\left(p_{1} \wedge \ldots \wedge p_{n} \Rightarrow q\right)$ and $\theta^{\prime} \leftarrow \operatorname{UNIFY}\left(q, q^{\prime}\right)$ succeeds
ans $\leftarrow \operatorname{FOL}-\mathrm{BC}-\operatorname{Ask}\left(K B,\left[p_{1}, \ldots, p_{n} \mid \operatorname{Rest}(\right.\right.$ goals $\left.\left.)\right], \operatorname{Compose}\left(\theta, \theta^{\prime}\right)\right) \cup$ ans return ans
$\operatorname{SUBST}\left(\operatorname{COMPOSE}\left(\theta_{1}, \theta_{2}\right), \mathrm{p}\right)=$
$\operatorname{SUBST}\left(\theta_{2}, \operatorname{SUBST}\left(\theta_{1}, \mathrm{p}\right)\right)$

## Backward chaining example

Criminal(West)

## Backward chaining example

## Backward chaining example

## Backward chaining example

## Backward chaining example

## Backward chaining example

## Backward chaining example

## Backward chaining example

## Properties of backward chaining

- Depth-first recursive proof search: space is linear in size of proof
- Incomplete due to infinite loops
$-\Rightarrow$ fix by checking current goal against every goal on stack
- Inefficient due to repeated subgoals (both success and failure)
$-\Rightarrow$ fix using caching of previous results (extra space)
- Widely used for logic programming

## Logic programming: Prolog

- Algorithm = Logic + Control
- Basis: backward chaining with Horn clauses + bells \& whistles Widely used in Europe, Japan (basis of 5th Generation project) Compilation techniques $\Rightarrow 60$ million LIPS
- Program = set of clauses = head :- literal ${ }_{1}$, ... literal ${ }_{n}$. criminal(X) :- american(X), weapon(Y), sells(X,Y,Z), hostile(Z).
- Depth-first, left-to-right backward chaining
- Built-in predicates for arithmetic etc., e.g., $X$ is $Y * Z+3$
- Built-in predicates that have side effects (e.g., input and output
- predicates, assert/retract predicates)
- Closed-world assumption ("negation as failure")
- e.g., given alive(X) :- not dead(X).
- alive(joe) succeeds if dead (joe) fails

## Prolog

- Appending two lists to produce a third:

```
append([],Y,Y).
append([X|L],Y,[X|Z]) :- append(L,Y,Z).
```

- query:

$$
\text { append }(A, B,[1,2]) \text { ? }
$$

- answers:

$$
\begin{array}{ll}
A=[] & B=[1,2] \\
A=[1] & B=[2] \\
A=[1,2] & B=[]
\end{array}
$$

## Resolution: brief summary

- Full first-order version:
$\frac{\mathcal{S}_{1} \vee \cdots \vee \zeta_{k}, \quad m_{1} \vee \cdots \vee m_{n}}{\left(C_{1} \vee \cdots \vee \zeta_{i-1} \vee \zeta_{i+1} \vee \cdots \vee \zeta_{k} \vee m_{1} \vee \cdots \vee m_{j-1} \vee m_{j+1} \vee \cdots \vee m_{n}\right) \theta}$ where $\operatorname{Unify}\left(\varsigma_{\mathrm{j}}, \neg m_{j}\right)=\theta$.
- The two clauses are assumed to be standardized apart so that they share no variables.
- For example,

$$
\begin{gathered}
\neg \operatorname{Rich}(x) \vee \begin{array}{c}
\text { Unhappy }(x) \\
\text { Rich }(\text { Ken })
\end{array} \\
\hline \text { Unhappy }(\text { Ken })
\end{gathered}
$$

with $\theta=\{x /$ Ken $\}$

- Apply resolution steps to $\operatorname{CNF}(\mathrm{KB} \wedge \neg \mathrm{a})$; complete for FOL

## Conversion to CNF

- Everyone who loves all animals is loved by someone: $\forall x[\forall y \operatorname{Animal}(y) \Rightarrow \operatorname{Loves}(x, y)] \Rightarrow[\exists y \operatorname{Loves}(y, x)]$
- 1. Eliminate biconditionals and implications $\forall x[\neg \forall y \neg \operatorname{Animal}(y) \vee \operatorname{Loves}(x, y)] \vee[\exists y \operatorname{Loves}(y, x)]$
- 2. Move $\neg$ inwards: $\neg \forall x p \equiv \exists x \neg p, \neg \exists x p \equiv \forall x \neg p$ $\forall x[\exists y \neg(\neg$ Animal $(y) \vee \operatorname{Loves}(x, y))] \vee[\exists y \operatorname{Loves}(y, x)]$ $\forall x[\exists y \neg \neg$ Animal $(y) \wedge \neg \operatorname{Loves}(x, y)] \vee[\exists y \operatorname{Loves}(y, x)]$ $\forall x[\exists y \operatorname{Animal}(y) \wedge \neg \operatorname{Loves}(x, y)] \vee[\exists y \operatorname{Loves}(y, x)]$

## Conversion to CNF contd.

3. Standardize variables: each quantifier should use a different one
$\forall x[\exists y$ Animal( $y$ ) $\wedge \neg \operatorname{Loves}(x, y)] \vee[\exists z \operatorname{Loves}(z, x)]$
4. Skolemize: a more general form of existential instantiation. Each existential variable is replaced by a Skolem function of the enclosing universally quantified variables:
$\forall x[\operatorname{Animal}(F(x)) \wedge \neg \operatorname{Loves}(x, F(x))] \vee \operatorname{Loves}(G(x), x)$
5. Drop universal quantifiers:
$[$ Animal $(F(x)) \wedge \neg \operatorname{Loves}(x, F(x))] \vee \operatorname{Loves}(G(x), x)$
6. Distribute $\vee$ over $\wedge$ :
$[\operatorname{Animal}(F(x)) \vee \operatorname{Loves}(G(x), x)] \wedge[-\operatorname{Loves}(x, F(x)) \vee \operatorname{Loves}(G(x), x)]$

## Resolution proof: definite clauses
